Page 2 Description of Property & Operation

men working on G, H, and A levels. Figure SS-2 shows the general work areas on a generalized schematic diagram of the mine.

The mining method for extracting the ore is shrinkage stoping. Presently haulage drifts are driven in the ore with slusher drifts located 20 to 30 feet above the haulage. Future stopes will be developed with the haulage drifts in the footwall and short crosscuts over to the vein so the ore pillar presently left between the slusher and haulage drifts can be eliminated. A central timbered raise is driven between two levels before stoping begins and a cribbed riase is carried up at each end of the stope as the stoping progresses. No other timber is used in the stopes and only occasional timber support is necessary in the haulage drifts. Stopes are left unfilled after the ore has been removed and they usually stand for many years without caving. Many older stopes were mined with no connecting raises between levels, thus there are few travelways between levels below F level However, in general for each vein with raises (one or several) connecting two levels a representative raise will be shown. Most of the raises are travelable. The Sunnyside and Washington veins are connected continuously from F and A levels respectively, to surface but these connections are generally not travelable.

Access to the mine is through the approximately two mile long American Tunnel which is on the bottom level of the mine, A level, at an elevation of 10,600 feet. This tunnel is lightly timbered for short distances. A snow shed, a shop and some offices are located near the portal. Men and supplies are hoisted to H, G and F levels in the Washington Incline Shaft. This shaft, which is inclined 80 degrees is a timbered two compartment shaft. One compartment contains a man cage with a capacity of 15 men and a hoisting speed of 200 to 300 feet per minute. The other compartment contains pipes, cables, and a manway and the hoist rope for the hoist which is located on A level. Access to stopes above F level is either by climbing up the stope raises or riding timber slide skips which are operated by compressed air tugger hoists on F level.

Two shafts above F level, the Terry and Washington Vertical, are inactive and no longer equipped for hoisting. These two timbered shafts are not commected to surface, however old stopes close to the shaft collars are open to surface. A service raise is planned which will connect F level, and any active levels above to surface. The one mile long Terry Tunnel on the southeast end of F level connects to surface and is occasionally used for transporting supplies into the mine during the summer. The Terry portal is high on a mountain slope and is accessable by snow mobile in the winter. The Mogul raise also connects F level as well as B and No. 1 levels to surface, but this part of the mine is inactive and has not been travelled for some time.

Ore is hauled out of the mine through the American Tunnel by two 150 horsepower diesel locomotives which also serve to transport supplies into the mine. An ore pass near the Washington Incline Shaft is used to transfer ore from F, G, and H levels down to A level. On F level a 90 horsepower diesel locomotive and two 6-ton battery locomotives are used for transferring ore from the stope ore passes to the main ore pass and also for delivering supplies to the stopes. Battery locomotives are used on the other active levels for delivering supplies.

7

Page 3 Description of Property & Operation

The electric power to the mine is reduced from 17 KV to 4160 volts at the American Tunnel portal. A 4160 volt line runs through the American Tunnel and up the Washington Incline Shaft to F level. Substations near the hoist-room on A level near the shaft stations on H and G levels, and near the top of the Washington Incline as in the Terry Tunnel on F level transform the 4160 volts down to 440 volts for use in the mine.

The mine phone system connects the shaft stations on all levels below and including F level to surface through the Washington Incline and the AMerican Tunnel. There are few phones in the mine on separate circuits which connect the tops and bottom of several raises above F level. Consideration has been given to excending the present phone system to connect the active workings above F level to surface.

The main air compressor station, with a capacity of 2400 cfm, is at the bottom of the Washington Incline. A second compressor station, with a capacity of 600 cfm, is located near the inby end of the Terry Tunnel on F level. These two compressor stations are connected through the compressed air line which runs up the Washington Incline adn along F level with branch lines to the various work areas. A third compressor station, also with a 600 cfm capacity, is located on H level but is not in use. Drill water is pumped to the active headings from a sump on F level by 22 horsepower electric pump through water lines which generally parallel the compressed air lines.
